

Introduction to numerical projects

Here follows a brief recipe and recommendation on how to write a report for each project.

- Give a short description of the nature of the problem and the eventual numerical methods you have used.
- Describe the algorithm you have used and/or developed. Here you may find it convenient to use pseudocoding. In many cases you can describe the algorithm in the program itself.
- Include the source code of your program. Comment your program properly.
- If possible, try to find analytic solutions, or known limits in order to test your program when developing the code.
- Include your results either in figure form or in a table. Remember to label your results. All tables and figures should have relevant captions and labels on the axes.
- Try to evaluate the reliability and numerical stability/precision of your results. If possible, include a qualitative and/or quantitative discussion of the numerical stability, eventual loss of precision etc.
- Try to give an interpretation of your results in your answers to the problems.
- Critique: if possible include your comments and reflections about the exercise, whether you felt you learnt something, ideas for improvements and other thoughts you've made when solving the exercise. We wish to keep this course at the interactive level and your comments can help us improve it.
- Try to establish a practice where you log your work at the computerlab. You may find such a logbook very handy at later stages in your work, especially when you don't properly remember what a previous test version of your program did. Here you could also record the time spent on solving the exercise, various algorithms you may have tested or other topics which you feel worthy of mentioning.
- You should include tests of your algorithms. This could be represented by unit tests and/or tests of mathematical aspects of the algorithm.

Format for electronic delivery of report and programs

The preferred format for the report is a PDF file. You can also use DOC or postscript formats or as an ipython notebook file. As programming language we prefer that you choose between C/C++, Fortran2008 or Python. The following prescription should be followed when preparing the report:

- Use your github address to hand in your projects.
- Make a folder for each project. For each project you should have three folders: one for the code files, one for the report and finally a folder with specific benchmark calculations. The latter can be in the form of output from your code for a selected set of runs and input parameters.

Finally, we encourage you to work two and two together. Optimal working groups consist of 2-3 students. You can then hand in a common report.

Project 1, deadline February 12

The aim of this project is to get familiar with various vector and matrix operations, from dynamic memory allocation to the usage of programs in the library package of the course. For Fortran users memory handling and most matrix and vector operations are included in the ANSI standard of Fortran 90/95. Array handling in Python is also rather trivial. For C++ user however, there are several possible options. Two are listed here.

1. For this exercise we recommend that you make your own functions for dynamic memory allocation of a vector and a matrix. You don't need to write a class for this operations. Use then the library package `lib.cpp` with its header file `lib.hpp` for obtaining LU-decomposed matrices, solve linear equations etc.
2. A very good and often recommended library for C++ handling of arrays is the library Armadillo, to be found at arma.sourceforge.net. We will discuss the usage of this library during the lab sessions and lectures. Armadillo has also an interface to Lapack functions for solving systems of linear equations.

Your program, whether it is written in C++, Python or Fortran2008, should include dynamic memory handling of matrices and vectors.

The material needed for this project is covered by chapter 6 of the lecture notes, in particular section 6.4 and subsequent sections.

Many important differential equations in the Sciences can be written as linear second-order differential equations

$$\frac{d^2y}{dx^2} + k^2(x)y = f(x),$$

where f is normally called the inhomogeneous term and k^2 is a real function.

A classical equation from electromagnetism is Poisson's equation. The electrostatic potential Φ is generated by a localized charge distribution $\rho(\mathbf{r})$. In three dimensions it reads

$$\nabla^2\Phi = -4\pi\rho(\mathbf{r}).$$

With a spherically symmetric Φ and $\rho(\mathbf{r})$ the equations simplifies to a one-dimensional equation in r , namely

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{d\Phi}{dr} \right) = -4\pi\rho(r),$$

which can be rewritten via a substitution $\Phi(r) = \phi(r)/r$ as

$$\frac{d^2\phi}{dr^2} = -4\pi r\rho(r).$$

The inhomogeneous term f or source term is given by the charge distribution ρ multiplied by r and the constant -4π .

We will rewrite this equation by letting $\phi \rightarrow u$ and $r \rightarrow x$. The general one-dimensional Poisson equation reads then

$$-u''(x) = f(x).$$

- (a) In this project we will solve the one-dimensional Poisson equation with Dirichlet boundary conditions by rewriting it as a set of linear equations.

To be more explicit we will solve the equation

$$-u''(x) = f(x), \quad x \in (0, 1), \quad u(0) = u(1) = 0.$$

and we define the discretized approximation to u as v_i with grid points $x_i = ih$ in the interval from $x_0 = 0$ to $x_{n+1} = 1$. The step length or spacing is defined as $h = 1/(n+1)$. We have then the boundary conditions $v_0 = v_{n+1} = 0$. We approximate the second derivative of u with

$$-\frac{v_{i+1} + v_{i-1} - 2v_i}{h^2} = f_i \quad \text{for } i = 1, \dots, n,$$

where $f_i = f(x_i)$. Show that you can rewrite this equation as a linear set of equations of the form

$$\mathbf{A}\mathbf{v} = \tilde{\mathbf{b}},$$

where \mathbf{A} is an $n \times n$ tridiagonal matrix which we rewrite as

$$\mathbf{A} = \begin{pmatrix} 2 & -1 & 0 & \dots & \dots & 0 \\ -1 & 2 & -1 & 0 & \dots & \dots \\ 0 & -1 & 2 & -1 & 0 & \dots \\ & \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & & -1 & 2 & -1 \\ 0 & \dots & & 0 & -1 & 2 \end{pmatrix} \quad (1)$$

and $\tilde{b}_i = h^2 f_i$.

In our case we will assume that the source term is $f(x) = 100e^{-10x}$, and keep the same interval and boundary conditions. Then the above differential equation has a closed-form solution given by $u(x) = 1 - (1 - e^{-10})x - e^{-10x}$ (convince yourself that this is correct by inserting the solution in the Poisson equation). We will compare our numerical solution with this result in the next exercise.

- (b) We can rewrite our matrix \mathbf{A} in terms of one-dimensional vectors a, b, c of length $1 : n$. Our linear equation reads

$$\mathbf{A} = \begin{pmatrix} b_1 & c_1 & 0 & \dots & \dots & \dots \\ a_2 & b_2 & c_2 & \dots & \dots & \dots \\ & a_3 & b_3 & c_3 & \dots & \dots \\ & \dots & \dots & \dots & \dots & \dots \\ & & & a_{n-2} & b_{n-1} & c_{n-1} \\ & & & & a_n & b_n \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \\ \dots \\ \dots \\ \dots \\ v_n \end{pmatrix} = \begin{pmatrix} \tilde{b}_1 \\ \tilde{b}_2 \\ \dots \\ \dots \\ \dots \\ \tilde{b}_n \end{pmatrix}. \quad (2)$$

A tridiagonal matrix is a special form of banded matrix where all the elements are zero except for those on and immediately above and below the leading diagonal. The above tridiagonal system can be written as

$$a_i v_{i-1} + b_i v_i + c_i v_{i+1} = \tilde{b}_i, \quad (3)$$

for $i = 1, 2, \dots, n$. The algorithm for solving this set of equations is rather simple and requires two steps only, a decomposition and forward substitution and finally a backward substitution.

Your first task is to set up the algorithm for solving this set of linear equations. Find also the precise number of floating point operations needed to solve the above equations. Compare this with standard Gaussian elimination and LU decomposition.

Then you should code the above algorithm and solve the problem for matrices of the size 10×10 , 100×100 and 1000×1000 . That means that you choose $n = 10$, $n = 100$ and $n = 1000$ grid points.

Compare your results (make plots) with the closed-form solution for the different number of grid points in the interval $x \in (0, 1)$. The different number of grid points corresponds to different step lengths h .

- (c) Compute the relative error in the data set $i = 1, \dots, n$, by setting up

$$\epsilon_i = \log_{10} \left(\left| \frac{v_i - u_i}{u_i} \right| \right),$$

as function of $\log_{10}(h)$ for the function values u_i and v_i . For each step length extract the max value of the relative error. Try to increase n to $n = 10000$ and $n = 10^5$. Make a table of the results and comment your results.

- (d) Compare your results with those from the LU decomposition codes for the matrix of sizes 10×10 , 100×100 and 1000×1000 . Here you should use the library functions provided on the webpage of the course. Alternatively, if you use *armadillo* as a library, you can use the similar function for LU decomposition. The *armadillo* function for the LU decomposition is called *LU* while the function for solving linear sets of equations is called *solve*. Use for example the unix function *time* when you run your codes and compare the time usage between LU decomposition and your tridiagonal solver. Alternatively, you can use the functions in C++, Fortran or Python that measure the time used.

Make a table of the results and comment the differences in execution time How many floating point operations does the LU decomposition use to solve the set of linear equations? Can you run the standard LU decomposition for a matrix of the size $10^5 \times 10^5$? Comment your results.

To compute the elapsed time in c++ you can use the following statements

Time in C++

```
using namespace std;
...
#include "time.h"    // you have to include the time.h header
int main()
{
    // declarations of variables
    ...
    clock_t start, finish; // declare start and final time
    start = clock();
    // your code is here, do something and then get final time
    finish = clock();
```

```
( ( finish - start ) / CLOCKS_PER_SEC );  
...
```

Similarly, in Fortran, this simple example shows how to compute the elapsed time.

Time in Fortran

```
PROGRAM time  
REAL :: etime           ! Declare the type of etime()  
REAL :: elapsed(2)      ! For receiving user and system time  
REAL :: total           ! For receiving total time  
INTEGER :: i, j  
  
WRITE(*,*) 'Start'  
  
DO i = 1, 5000000  
    j = j + 1  
ENDDO  
  
total = ETIME(elapsed)  
WRITE(*,*) 'End: total=', total, ' user=', elapsed(1), &  
        ' system=', elapsed(2)  
  
END PROGRAM time
```
